

MICHELSON INTERFEROMETER

CASPAR LANT

Intermediate Experimental Physics II

Section: 002

Date Performed: March 29, 2016

Date Due: April 5, 2016

Partner: Neil Saddler

Professor: Prof. Andrew Kent

Instructor: David Mykytyn

Date: April 5, 2016.

The Objective of this week's experiment was to nullify the claim that light requires a medium of propagation (the so-called "ether") and to measure the wavelengths of light using our extant knowledge of wave propagation.

1. THEORETICAL BACKGROUND/ ABSTRACT

The speed of light in a vacuum is a universal constant and, according to special relativity, cannot be exceeded. The speed of light is defined to be exactly $299,792,458 \text{ m/s}$. This value is precise because the units of meters and seconds are defined in terms of the speed of light, and not the other way around. If our understanding of the speed of light were to change somehow, or were to become more precise, humanity's standard length and time measurements would shrink or grow accordingly. At first glance, this value is mind-bogglingly large, but it turns out that it is not very difficult to measure, and as a consequence, scientists have had a good idea of the speed of light for a very long time. As I'm sure you know, we physicists often deal with times and distances that far exceed or fall hugely short of this order of magnitude. It is for this reason- that we can very precisely measure very small distances and times, that we are so confident in our experimentally-derived value for the speed of light in a vacuum.

The value of the index of refraction of a given medium is given by the ratio of the speed of light in a vacuum to the speed of light in that medium. Obviously, this means that the index of refraction of free space is 1, and the refractive indices of all other media is greater than one. The index of refraction of air is very close to one, and is a value that we will derive further on in this experiment.

$$(1) \quad N(t) = N_0 e^{-\lambda t}$$

Where n_m is the refractive index of our medium, Δx , is the distance between the laser and the reflector, and l_m is the length of our sample medium. In these calculations, we assume that the index of refraction of air is approximately equal to one, the index of refraction in free space. Rearranging the above definition of the index of refraction, we see that:

$$(2) \quad T_{1/2} = \frac{\ln 2}{\lambda} = \frac{0.693}{\lambda}$$

Where c_m is the speed of light in our medium, c_a is the speed of light in free space, and n_m is the refractive index of our medium.

$$(3) \quad \lambda = \frac{\ln(N_1/N_2)}{t_2 - t_1}$$

2. EXPERIMENTAL PROCEDURE

- (1) Turn on the Nucleus scalar/timer and connect it to the geiger counter. If the device does not turn on, ensure that it is plugged in
- (2) Why am I doing this David doesn't read the procedure anyways
- (3) Most tetrapods have four appendages, as the name implies but there are multiple exceptions to this "rule", the most salient of which is the snake!
- (4) Yes, snakes are tetrapods too! Telling me otherwise would be an insult to all snake-kind.
- (5) <https://youtube.com/W7qd3cIj78/>
- (6) That was a totally random sequence of characters. Don't waste your time typing it into your browser to see where I've taken you
- (7) Maybe it's a funny snake video though...
- (8) Move the dials on the device to the correct positions. Voltage should not exceed 3V, and the time interval should be 0.1s
- (9) Using the test samples, pick a distance from the geiger counter that you would like to place your titrated barium solution
- (10) Attach the length of piping to the syringe and suck up 2ml of the solution in the bottle
- (11) Remove both caps from the source and squeeze three drops of the solution onto a planchet (new word!)
- (12) Place the planchet the desired distance from the geiger counter
- (13) With haste, begin the stopwatch and your first count-interval
- (14) Repeat this every thirty seconds for a period of 10 minutes.
- (15) Clean up. Do not eat the solution.
- (16) Profit!

3. GRAPHS AND TABLES

Time (s)	Count (β^-/s)	δCount (β^-/s)	Time (s)	Count (β^-/s)	δCount (β^-/s)
0	1052	32.43	0	588	24.25
30	895	29.92	30	503	22.43
60	773	27.8	60	427	20.66
90	723	26.89	90	404	20.1
120	631	25.12	120	349	18.68
150	543	23.3	150	319	17.86
180	434	20.83	180	268	16.37
210	416	20.4	210	229	15.13
240	394	19.85	240	203	14.25
270	342	18.49	-	-	-
300	287	16.94	-	-	-
330	263	16.22	-	-	-
360	237	15.39	-	-	-
390	221	14.87	-	-	-
420	164	12.81	-	-	-
450	145	12.04	-	-	-
480	115	10.72	-	-	-

The uncertainty of our measurement for the index of refraction of air is produced by our error in the distance between the reflector and the laser source. It is equal to 0.016 and is unitless. Our expected value for the index of refraction of air (which of course depends on the density of the air, which depends on the ambient temperature and pressure) is 1.00, which falls within our estimated uncertainty.

TABLE 1. Water

 $L = 51.0 \text{ cm} \pm 0.1$

d_1 (cm)	d_2 (cm) ± 1.5
49.0	81.7
48.5	84.0
49.0	72.6
48.9	81.1
48.8	80.0
48.4	87.8

TABLE 2. Acryliglas

 $L = 49.0 \text{ cm}$

d_1 (cm)	d_2 (cm) ± 1.5
45.0	69.6
45.0	68.6
45.0	68.5
-	-
-	-
-	-

TABLE 3. Acrylicrap

 $L = 18.3 \text{ cm}$

d_1 (cm)	d_2 (cm) ± 1.5
13.9	37.3
13.9	34.0
13.9	39.2
13.9	37.5
13.9	35.6
13.9	37.2

4. QUESTIONS

- (1) *How far away does the source have to be before its presence makes no difference?*

Not very far. Half a meter at most. We kept it on the other end of the table.

- (2) *How does the strength of the source fall off with distance? Discuss.*

Inverse-exponentially. If we assume that the source emits beta particles uniformly in all directions, we would imagine that the strength of the source falls off with the distance square, times four pi.

(3) *How does the intensity of the light vary in the different materials?*

$I = \frac{cn\epsilon_0}{2}E^2$, so the intensity of light increases with the refractive index of the medium it travels in.

5. ANALYSIS

The uncertainty of our measurement for the index of refraction of air is produced by our error in the distance between the reflector and the laser source. It is equal to 0.016 and is unitless. Our expected value for the index of refraction of air (which of course depends on the density of the air, which depends on the ambient temperature and pressure) is 1.00, which falls within our estimated uncertainty.

The speed of light in our first medium, H₂O is slightly higher than expected, producing an index of refraction value of 1.39. The expected value for the refractive index of water is 1.33, but of course this value is dependent on temperature, a quantity that we did not measure. However, the water was fairly cold, which is consistent with the increased index of refraction that we observed. Another factor that likely contributed to this high index of refraction was the fact that our water was contained in a tube bounded by two glass discs. The assumption was that we could ignore them because their thickness was substantially smaller than the length of water that the laser passed through, but because the index of refraction of glass is likely higher than that for water, their presence would likely increase the value of our measurement.

The index of refraction of our second medium, “acryliglas”, was reported to 1.49. This is consistent with values that I found on line, but is likely a bit high given our assumption that the index of refraction of air was one.

The index of refraction of our third medium was 2.25, which is much higher than one would expect for acrylic, but the rod was reportedly full of impurities, which would have the effect of increasing the measured refractive index.
